Overview and Objectives

The ET1210 AC/DC electronics final typically entails designing a power supply circuit capable of converting alternating current (AC) from mains electricity into direct current (DC) suitable for various electronic devices. The main objectives include:

- Designing a reliable and efficient rectification stage
- Implementing filtering techniques to smooth out voltage ripple

- Ensuring safety and compliance with electrical standards

This project not only tests theoretical knowledge but also emphasizes practical skills such as circuit assembly, troubleshooting, and performance evaluation.

Core Components of AC/DC Power Supply

Rectifiers

Rectification is the process of converting AC to DC. The two main types are:

- **Half-wave rectifier:** Uses a single diode to convert only one half-cycle of AC, resulting in a pulsating DC with high ripple.
- **Full-wave rectifier:** Uses four diodes (bridge rectifier) or a center-tapped transformer to convert both half-cycles, providing smoother DC.

For most ET1210 final projects, a full-wave bridge rectifier is preferred for efficiency.

Filters

Filtering reduces the ripple from the rectified output. Common filtering components include:

- **Capacitors:** Large electrolytic capacitors are used to smooth the pulsating DC.
- **Inductors:** Used in LC filters for additional ripple reduction.

The size of the filter capacitor directly impacts the smoothness and stability of the output voltage.

Voltage Regulation

To achieve a stable DC output, voltage regulators are employed:

- **Linear regulators:** Simple and provide low noise but are less efficient.
- **Switching regulators:** More efficient, suitable for higher power applications.

Common voltage regulator ICs include 7805 (for +5V output) and similar devices.
